## E - Most Valuable Parentheses (/contests/abc407/tasks/abc407\_e) Editorial by en\_translator (/users/en\_translator)

Among various equivalent definitions of a correct parenthesis sequence, one of the most intuitive one is:

- For  $1 \leq i \leq 2N$ , among  $S_1, \dots, S_i$ , at least  $\frac{i}{2}$  characters are  $($ .
- Among  $S_1, \dots, S_{2N}$ , exactly  $N$  characters are  $($ .

Taking the " $\frac{i}{2}$ " as the variable, we can further rephrase it like this:

- For all  $1 \leq k \leq N$ , among  $S_1, \dots, S_{2k-1}$ , at least  $k$  characters are  $($ .
- Among  $S_1, \dots, S_{2N}$ , exactly  $N$  characters are  $($ .

This definition suggests the following procedure to construct a parenthesis sequence:

1. Determine  $S_1 = ($ . (Regard this step as  $k = 1$  for convenience.)
2. For  $2 \leq k \leq N$  in ascending order:
  - Add  $2k - 2, 2k - 1$  to the set of candidates.
  - Choose one element  $x$  from the set of candidates and remove it. Determine  $S_x = ($ .
3. Set the undetermined  $N$  characters to be  $)$ .

This procedure indeed yields a correct parenthesis sequence, and any correct parenthesis sequence can be constructed by this procedure.

# Proof that the parenthesis sequences generated by this procedure are equal to the correct parenthesis sequences

Take a sequence  $S$  constructed by this procedure. For all  $1 \leq t \leq N$ ,

- For all  $k$  with  $1 \leq k \leq t$ , at least one of  $S_1, \dots, S_{2t-1}$  is set  $($ , so at least  $t$  characters among  $S_1, \dots, S_{2t-1}$  is  $($ .
- There are exactly  $N$   $($ 's.

Hence,  $S$  is a correct parenthesis sequence.

Conversely, take a correct parenthesis sequence  $S$ . For all  $1 \leq t \leq N$ ,

- $S_1$  is  $($ .
- At least  $t$  characters among  $S_1, \dots, S_{2t-1}$  is  $($ . When  $k = t$ , only  $(t - 1)$  elements have been chosen to be  $($ , so there is at least one element that can be chosen for  $k = t$ .
- There are exactly  $N$   $($ 's.

Hence,  $S$  can be constructed by the procedure. **(End of proof)**

Here, one can prove as follows that the final score of  $S$  can be maximized by, when choosing an element  $x$  from the set of candidate, picking the one that maximizes  $A_x$ .

## The proof that the greedy algorithm is valid

Suppose that when  $k = t$ , while  $A_x$  is the maximum element, we instead choose  $A_y$  ( $< A_x$ ).

- If  $A_x$  is not chosen for any  $k > t$ : by picking  $A_x$  instead of  $A_y$  and choosing the same elements for the other  $k$ , the procedure is still valid, but the score of  $S$  increases.
- If  $A_x$  is chosen for some  $k = t' > t$ : by choosing  $A_x$  for  $k = t$  and choosing  $A_y$  for  $k = t'$ , while choosing the same elements for the other  $k$ , the procedure is still valid, but the score of  $S$  increases.

In any case, there is a better choice to improve the final score of  $S$ . Therefore, choosing  $A_y$  ( $< A_x$ ) for  $k = t$  is not optimal, and thus choosing  $A_x$  is optimal. **(End of proof)**

The implementation can be simplified by using a priority queue. (C++ has a standard library `std::priority_queue`.)

The sample code in C++ is shown below.

Copy

```
1. #include <iostream>
2. #include <vector>
3. #include <queue>
4. using std::cin;
5. using std::cout;
6. using std::cerr;
7. using std::endl;
8. using std::vector;
9. using std::priority_queue;
10. using std::greater;
11.
12.
13. typedef long long ll;
14.
15. ll solve (const ll n, const vector<ll> &a) {
16.     ll ans = 0;
17.
18.     priority_queue<ll, vector<ll> > que;
19.     for (ll i = 0; i < n; i++) {
20.         if (i == 0) {
21.             que.push(a[i*2-0]);
22.         } else {
23.             que.push(a[i*2-1]);
24.             que.push(a[i*2-0]);
25.         }
26.
27.         ll v = que.top();
28.         que.pop();
29.
30.         ans += v;
31.     }
32.
33.     return ans;
34. }
35.
36. int main (void) {
37.     int T;
38.     cin >> T;
39.     while (T--) {
40.         ll n;
41.         cin >> n;
42.         vector<ll> a(n*2);
43.         for (ll i = 0; i < n*2; i++) {
44.             cin >> a[i];
45.         }
46.
47.         cout << solve(n, a) << "\n";
```

2025-05-24 (Sat)  
23:46:52 -04:00

```
48.      }  
49.  
50.      return 0;  
51. }
```
